

The following data definition statements mean the same thing:

```
int* ptr;
```

```
int *ptr;
```

```
int * ptr;
```

```
int          *          ptr;
```

```
int*          ptr;
```

```
int* ptr;
```

```
int n;
```

```
ptr = &n;
```

`type(n) == int` ... assigned by programmer.

`type(&n) == int*` ... because of `&n` is an address of which `n` is a name.

```
float f_num;
```

`type(f_num) == float` ... assigned by programmer

`type(&f_num) == float*`

```
struct Date myDate;
```

`type(myDate) == struct Date`

`type(&myDate) == struct Date*`

`type(n) == int`

```
int m;
```

```
m = n;
```

`type(n) == int & type(m) == int` (lhs type == rhs type)

ptr = &n;

type(n) == int ... assigned by programmer

type(&n) == int*

type(ptr) == int* .. assigned by programmer

ptr = &n;

int* ptr;

int n;

ptr = &n;

Base address of n is stroed in ptr.

lhs = rhs; // rhs expression is evaluated to a data value

 // lhs expression is evaluated to a location value (i.e. address in memory)

 // assignment operator says: store data value (which is a result of evaluation of rhs)

 // at a location value (which is a result of evaluation of rhs)

int* ptr; 5000: 
 (ptr)

int n; 2000: 
 (n)

int m = n; [eval: 600]

int* ptr = &n; [eval: 2000]

$$n = 700;$$

$700 = rhs = 700 = \text{data value.}$

$n = lhs = M[2000] = \text{location value.}$

5000: (ptr) 2000 | after ptr = &n;

2000: (n) 600

$$ptr = 700;$$

$$* ptr = 700;$$

$$rhs = 700 = rhs \text{ value } \underline{700}$$

Case 1: $ptr = 700;$

LHS expression = ptr

after evaluation $M[5000]$ will be the location value.

Therefore, 700 will be stored at memory location starting from $M[5000]$.

i.e. 2000 which is a base address of integer n , which was stored at $M[5000]$ will be ERASED and replaced by 700 (which may not be base address of any integer)

Case 2:

`*ptr = 700;`

`rhs = 700`

after evaluation : integer 700 will be an evaluation of the rhs expression.

`rhs value = 700`

Lets find out a location value for 700.

lhs expression == `*ptr`

CONTENT stored INSIDE `ptr` is TAKEN as a LOCATION VALUE instead of LOCATION WHOSE NAME IS `ptr`.

In our case `ptr` is a name of `M[5000]`

2000 is a CONTENT stored at `M[5000]`

`*ptr` is a LEFT HAND SIDE EXPRESSION

CONTENT STORED INSIDE `ptr` == 2000

is a LOCATION VALUE, instead of LOCATION 5000 (whose name is `ptr`)

700 will be stored at `M[2000]` which is nothing but base address of `n`.

Therefore, we will get effect of erasing 600 of `n` and replacing it with 700.

```
int n;
```

```
n = 10;
```

```
int* ptr;
```

```
ptr = &n;
```

```
int n = 10;
```

```
int* ptr = &n;
```

```
void f(void)
{
    int * ptr;
    ptr = &n;
    ptr = 1547;
    *ptr;
}
```

T* ptr;

lhs = *ptr;

*ptr he expression rhs la theun, C programmer, C compiler la, ase sangat asto, ki ptr hya variable madhali value address mhanun treat kar ani tya address pasun sizeof(ptr type) evadhe bytes read kar

*ptr = rhs;

*ptr he expression lhs la theun, C programmer, C compiler la ase sangat asto ki, ptr hya variable madhali value address mhanun treat kar ani tya address pasun sizeof(ptr type) evadhya bytes var rhs_value write kar.

lhs = *ptr;

By writing *ptr expression on rhs, a C programmer asks the C compiler to treat value in ptr as an address and read sizeof(ptr type) bytes from that address.

*ptr = rhs;

By writing *ptr expression on lhs, a C programmer asks the C compiler to treat value in ptr as an address and write rhs_value on sizeof(ptr type) bytes from that address.

CAREER DEFINING.
